Artificial Intelligence

Chapter 3 (part 2): Heuristic Search

Adapted from slides available in Russell & Norvig's textbook webpage

Dr. Ahmedul Kabir

Outline

- Heuristics
- Best-first search
- Greedy best-first search
- A^* search
- More on heuristics

Definition of heuristics

- A **heuristic technique** (/hjuːˈrɪstɪk/; Ancient Greek: εὕρισκω, "find" or "discover"), often called simply a heuristic, is any approach to problem solving, learning, or discovery that employs a practical method not guaranteed to be optimal or perfect, but sufficient for the immediate goals.
- Heuristics can be mental shortcuts that ease the cognitive load of making a decision.
- Examples of this method include using a **rule of thumb**, an **educated guess**, or **common sense**.

Example: Driving from A to B

- The straight line distance is a heuristic to estimate the driving distance

Example: 8-puzzle problem

1	2	3
8		4
7	6	5

2	8	3
1	6	4
7		5

	1	2
3	4	5
6	7	8

Which state is “closer” to the goal state?
How can we quantify this?

Best-first search

- Idea: use an **evaluation function** $f(n)$ for each node
 - estimate of "desirability"
- Expand **most desirable** unexpanded node
- Implementation:

Order the nodes in fringe in decreasing order of desirability
- Special cases:
 - Greedy best-first search
 - A^* search

Romania with step costs in km

Straight-line distance
to Bucharest

Arad	366
Bucharest	0
Craiova	160
Dobreta	242
Eforie	161
Fagaras	176
Giurgiu	77
Hirsova	151
Iasi	226
Lugoj	244
Mehadia	241
Neamt	234
Oradea	380
Pitesti	10
Rimnicu Vilcea	193
Sibiu	253
Timisoara	329
Urziceni	80
Vaslui	199
Zerind	374

Greedy best-first search

- Evaluation function $f(n) = h(n)$ (**h**euristic)
= estimate of cost from n to *goal*
- e.g., $h_{SLD}(n)$ = straight-line distance from n to Bucharest
- Greedy best-first search expands the node that **appears** to be closest to goal

Greedy best-first search example

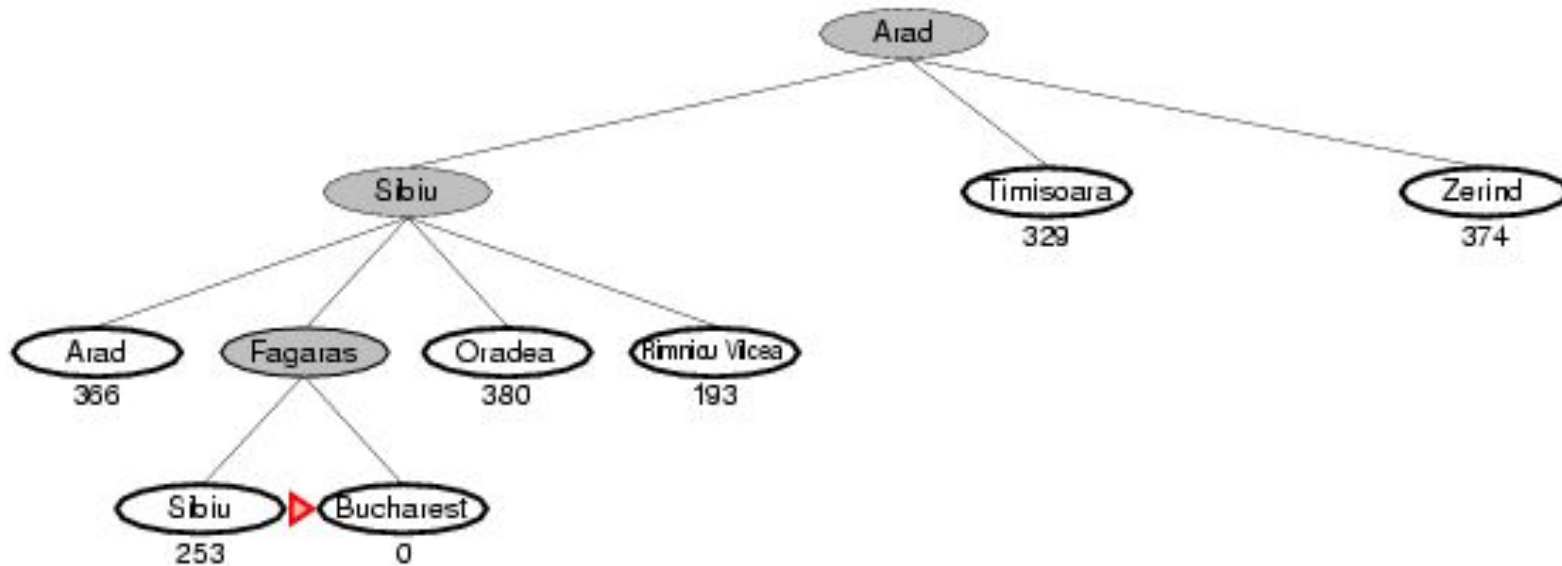

Greedy best-first search example

Greedy best-first search example

Properties of greedy best-first search

- Complete? No – can get stuck in loops, e.g., when going from Iasi to Fagars:

Iasi Neamt Iasi Neamt

- Time? $O(b^m)$, but a good heuristic can give dramatic improvement
- Space? $O(b^m)$ -- keeps all nodes in memory
- Optimal? No

A^{*} search

- Idea: avoid expanding paths that are already expensive
- Evaluation function $f(n) = g(n) + h(n)$
- $g(n)$ = cost so far to reach n
- $h(n)$ = estimated cost from n to goal
- $f(n)$ = estimated total cost of path through n to goal

Admissible heuristics

- A heuristic $h(n)$ is **admissible** if for every node n , $h(n) \leq h^*(n)$, where $h^*(n)$ is the **true** cost to reach the goal state from n .
- An admissible heuristic **never overestimates** the cost to reach the goal, i.e., it is **optimistic**
- Example: $h_{SLD}(n)$ (never overestimates the actual road distance)
- **Theorem:** If $h(n)$ is admissible, A^* using TREE-SEARCH is optimal

Optimality of A^* (proof)

- Suppose some suboptimal goal G_2 has been generated and is in the fringe. Let n be an unexpanded node in the fringe such that n is on a shortest path to an optimal goal G .

- We need to show: $f(n) < f(G_2)$
- $f(n) = g(n) + h(n)$
 $\leq g(n) + c(n, G)$ since h is admissible
 $= g(G)$
 $< g(G_2)$ since G_2 is suboptimal
 $= f(G_2)$ since $h(G_2) = 0$

Properties of A^*

- Complete? Yes (unless there are infinitely many nodes with $f \leq f(G)$)
- Time? Exponential
- Space? Keeps all nodes in memory
- Optimal? Yes

Admissible heuristics

E.g., for the 8-puzzle:

- $h_1(n)$ = number of misplaced tiles
- $h_2(n)$ = total Manhattan distance
(i.e., no. of squares from desired location of each tile)

7	2	4
5		6
8	3	1

Start State

	1	2
3	4	5
6	7	8

Goal State

- $h_1(S) = ?$
- $h_2(S) = ?$

Admissible heuristics

E.g., for the 8-puzzle:

- $h_1(n)$ = number of misplaced tiles
- $h_2(n)$ = total Manhattan distance
(i.e., no. of squares from desired location of each tile)

7	2	4
5		6
8	3	1

Start State

	1	2
3	4	5
6	7	8

Goal State

- $h_1(S) = ?$ 8
- $h_2(S) = ?$ $3+1+2+2+2+3+3+2 = 18$

Dominance

- If $b_2(n) \geq b_1(n)$ for all n (both admissible)
- then b_2 **dominates** b_1
- b_2 is better for search
- Typical search costs (average number of nodes expanded):
 - $d=12$ IDS = 3,644,035 nodes
 $A^*(h_1) = 227$ nodes
 $A^*(h_2) = 73$ nodes
 - $d=24$ IDS = too many nodes
 $A^*(h_1) = 39,135$ nodes
 $A^*(h_2) = 1,641$ nodes
- Why is A^* so much better?
 Because it reduces the **effective branching factor**

Relaxed problems

- A problem with fewer restrictions on the actions is called a **relaxed problem**
- The cost of an optimal solution to a relaxed problem is an admissible heuristic for the original problem
- If the rules of the 8-puzzle are relaxed so that a tile can move **anywhere**, then $h_1(n)$ gives the shortest solution
- If the rules are relaxed so that a tile can move to **any adjacent square**, then $h_2(n)$ gives the shortest solution
